CALIBRATION AND SETUP INSTRUCTIONS

CALIBRATION

The FoamPro System 1600/1601 and flowmeter have been calibrated at the factory. To recalibrate the system, the following procedure may be followed:

1. Turn the CAL/INJECT valve to the CALIBRATE or FLUSH position. Provide a container to collect the output that will be coming from the foam pump.
2. Start the main water flow and set it to a known rate and pressure.
3. Set the injection rate to any specific setting (usually 0.5% or 1.0%).
4. Turn on the Model 1600/1601 and run it for 3 to 5 minutes. Foam will pump into the container.
5. Measure the amount of foam in the container and compare that to the calculated amount (main flow rate X injection rate X minutes flowed [100 gpm, X 0.005 (0.5%) injection rate, X 5 minutes = 2.5 gal. output]). If the amounts are significantly different, remove the small black screw and o-ring on the motor driver box with a 3/32 allen wrench. With a small slotted screwdriver, adjust the screw inside the driver module. If the measured flow is above what is expected, turn the screw clockwise. If the measured flow is below what is expected, turn the screw counterclockwise.
6. Repeat Steps 1 through 5 again and make any further adjustments required.
7. Replace the adjustment cover screw after calibration has been completed. This keeps water and dirt from entering the driver module and prevents serious damage to the unit.

NOTE: The viscosity of different foam concentrates may have an effect on the amount of foam concentrate that is injected into the water stream. When calibrating the system, use the foam concentrate that will be used most frequently during normal operations. When different viscosity foam concentrates are used, the actual concentrate injection may vary as much as 10%.

PRESSURE RELIEF VALVE ADJUSTMENT

The pressure relief valve is factory tested and preset at 400 psi (28 BAR). During normal installation and operation the relief valve will not require adjustment. The following procedures are provided if adjustment is necessary in field installation. DO NOT set the relief valve above 400 psi [28 BAR].

Perform this adjustment after the foam pump has been primed.

1. Determine the maximum pressure that will be needed to discharge foam solution. (For example: The maximum foam injection pressure should be approximately 50 psi [3.5 BAR] higher than the maximum operating pressure as set forth by department policy.)
2. Gather the items required for reading concentrate injection pressure. A 0-500 psi [0 to 34.5 BAR] test quality gauge, 500 psi [34.5 BAR] hoses and fittings to connect to the injector line from the foam pump.
3. Disconnect the injector from the foam line and connect the pressure gauge to it.
4. Screw the pressure adjustment nut on top of the valve all of the way down until it stops.
5. Unscrew the pressure adjustment nut counterclockwise 10 full turns. This will place it in a position to relieve at low pressure.
CAUTION: DO NOT run FoamPro 1600/1601 for more than one minute dead headed against the pressure gauge as the foam pump will overheat.
6. Operate the foam pump as described in the Foam Pump Priming Check Section.
7. While the foam pump is running, slowly screw the Pressure Adjustment Nut down clockwise until the desired pressure is reached. Apply tamper proof type sealant to pressure relief valve adjustment nut so that it does not move accidentally.
8. Stop the foam pump.
WARNING: Slowly loosen the foam pressure line fittings and allow the pressure to escape. Protect face and eyes from any potential spray which may occur.
9. Reconnect the foam line to the injector fitting. The pressure relief valve is now set.

1 gallon = 3.785 liters or 0.833 Imp. Gal.
